A Simple Workflow for Processing and Visualizing Experimental Data

The Author

February 21, 2026

Abstract

This short article demonstrates a minimal data workflow for reading raw data, applying basic processing steps, and generating figures for reporting. The pipeline is intentionally lightweight and serves as a template for reproducible analysis and visualization.

1 Introduction

Scientific results often rely on repeatable transformations from raw measurements to processed signals and summary figures [3, 4]. This demo project shows an end-to-end workflow that reads tabular data, applies smoothing and derivative calculations, and produces publication-ready plots [2].

2 Methods

Raw data are read from `data/raw.csv`. The processing script performs the following steps:

- drops rows with missing values,
- detects a time column when available (or uses row index),
- computes a moving-average smooth for numeric columns, and
- computes time derivatives for numeric columns.

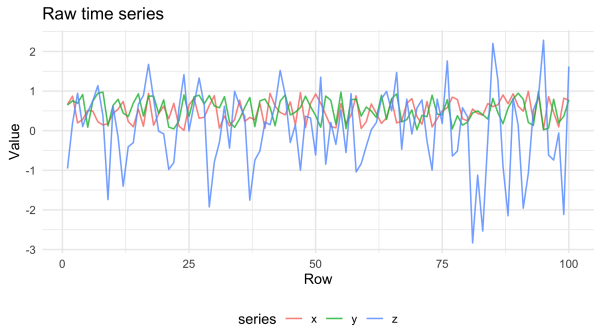
Processed data are written to `data/processed.csv`. The visualization script creates time-series and distribution plots for both raw and processed data, as well as plots for smoothed signals and derivatives when available [1].

3 Results

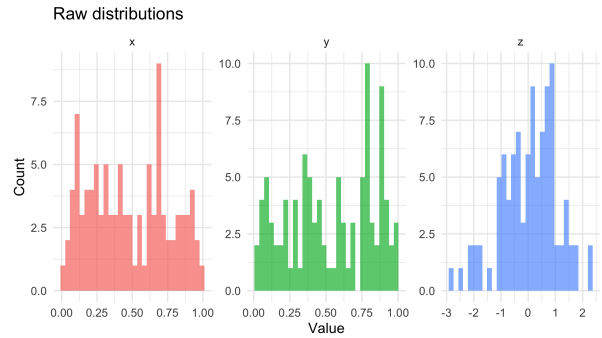
Figure 1 shows raw time-series and distributions. Figure 2 shows advanced visualizations. Figure 3 shows processed time-series, smoothed signals, and time derivatives.

4 Discussion

This demo highlights a reproducible workflow that turns raw tabular data into processed signals and figures suitable for inclusion in a report. The scripts can be extended with domain-specific processing and more refined visualization styles.



(a) Raw time series.



(b) Raw distributions.

Figure 1: Raw data visualizations.

5 Conclusion

The provided scripts and figures form a compact, reproducible analysis pipeline. They can be adapted for small experiments or larger studies with minimal modifications.
